PROPERTIES OF STATISTICS CONNECTED WITH
MINIMAL SPACING
AND RECORD EXCEEDANCES

I. Bairamov and S. Eryılmaz

SUMMARY

An additional insight to the distributional properties of statistics based on minimal spacing and record exceedances is provided. Behaviour of a sequence of independent identically distributed random variables with respect to a random threshold constructed by the help of minimal spacing and records is studied.

1. INTRODUCTION

This paper attempts to provide an additional insight into properties of exceedances and placement statistics described in Bairamov and Eryılmaz (2000). The importance of these concepts in construction of non-parametric tests of equality (identity) of distributions has been demonstrated by Katzenbeisser (1985), (1986), Matveychuk and Petunin (1990), Johnson and Kotz (1991), (1994), Wesolowsky and Ahsanullah (1998), Bairamov, Gebizlioglu and Kaya (1999). Our study is also related to the theory of invariant confidence intervals which contain the main distributed mass or future observations. Invariant confidence intervals which involve future observations are similar to, but not identical with, the approach of tolerance limits. Tolerance limits are originally introduced by Shewart (1931). Tolerance limits and exceedance statistics are widely discussed be Wilks (1941), Robbins (1944), Gumbel and Shelling (1950), Epstein (1954), Sarkadi (1957), Siddiqui (1977) along with others. Further detailed discussion can be found in
Invariant confidence intervals containing the main distributed mass were introduced in 1990 (c.f., Bairamov and Petunin (1991)). We mention here the definition and some results concerning invariant intervals. Let $X_1, X_2, ..., X_n$ be a random sample of size $n$ with distribution function (d.f.) $F$ in $\mathcal{F}$, $\mathcal{F}$ is some class of d.f.’s. $f_1(.)$ and $f_2(.)$ are assumed to be two Borel functions satisfying $f_1(x_1, x_2, ..., x_n) \leq f_2(x_1, x_2, ..., x_n)$, $\forall (x_1, x_2, ..., x_n) \in \mathbb{R}^n$. The random interval $(f_1(X_1, X_2, ..., X_n), f_2(X_1, X_2, ..., X_n))$ is called an invariant confidence interval containing the main distributed mass (or invariant confidence interval containing the future observations) for class $\mathcal{F}$, if $\exists \beta \in (0, 1)$ such that $P \{X_{n+1} \in (f_1(X_1, X_2, ..., X_n), f_2(X_1, X_2, ..., X_n))\} = \beta$, $\forall F \in \mathcal{F}$. The quantity $\beta$ is the same for all $F \in \mathcal{F}$ and is called a confidence level of an invariant interval. Let $\mathcal{F} = \mathcal{F}_c$ be the class of all continuous d.f.’s. It is known that under some natural conditions any invariant confidence interval for the class $\mathcal{F}_c$ can be generated only by the order statistics, so that $f_1(X_1, X_2, ..., X_n) = X_{(i)}$, $f_2(X_1, X_2, ..., X_n) = X_{(j)}$, $1 \leq i < j \leq n$, where $X_{(1)} < X_{(2)} < ... < X_{(n)}$ are order statistics generated by $X_1, X_2, ..., X_n$, which is defined with probability 1 (c.f., Bairamov and Petunin (1991)), and $P \{X_{n+1} \in (X_{(i)}, X_{(j)})\} = (j - i)/(n + 1)$.

Let $\{X_n\}_{n \geq 1}$ be a sequence of i.i.d. random variables with continuous d.f. $F(x)$. Let $X_{(1)} < X_{(2)} < ... < X_{(n)}$ be the almost sure (a.s.) defined order statistics generated by $X_1, X_2, ..., X_n$. Consider the spacings $X_{(1)} - X_{(0)}$, $X_{(2)} - X_{(1)}$, $X_{(3)} - X_{(2)}$, ..., $X_{(n)} - X_{(n-1)}$ with $X_{(0)} = \alpha(F) = \inf \{x : F(x) = 0\}$. Define a random variable $\nu$ as follows: $\nu = k$ iff $X_{(k)} - X_{(k-1)} \leq X_{(i)} - X_{(i-1)}$, $i = 1, 2, ..., n$. It is clear that $\nu$ is the index of a spacing having minimal length. Bairamov and Eryilmaz (2000) show that if $F(x) = 1 - \exp(-\lambda x)$, $x \geq 0$, $\lambda > 0$, then, for $s = 0, 1, ..., m$,

$$P \{X_{n+1}, X_{n+2}, ..., X_{n+s} \in (X_{(\nu-1)}, X_{(\nu)}), X_{n+s+1}, ..., X_{n+m} \notin (X_{(\nu-1)}, X_{(\nu)})\}$$

$$= \frac{2}{n+1} \sum_{i=0}^{m-s} (-1)^i \binom{m-s}{i} \frac{n+s+i+1}{s+i+2} \left(\binom{n(n+1)}{2} - s + i\right)^{-1}$$

$$s = 0, 1, 2, ..., m,$$

where $X_{(0)} = 0$. Let $S_m$ be the number of $k$, $k \in \{n+1, ..., n+m\}$, such that $X_k \in (X_{(\nu-1)}, X_{(\nu)})$. Denote by $A(m, n, s)$ the right hand side (r.h.s.)
An almost straightforward consequence of (1) is that
\[
P \{ S_m = s \} = \binom{m}{s} A(m, n, s), \quad s = 0, 1, 2, \ldots, m. \tag{2}
\]

2. ASYMPTOTIC DISTRIBUTION OF STATISTICS BASED ON MINIMAL SPACING

Let \( X_1, X_2, \ldots, X_n \) be an independent copies of nonnegative random variable having continuous distribution with d.f. \( F \). Also, let \( X_{(1)} < X_{(2)} < \ldots < X_{(n)} \) be order statistics constructed on the basis of \( X_1, X_2, \ldots, X_n \). Consider the spacings \( X_{(1)} - X_{(0)}, X_{(2)} - X_{(1)}, X_{(3)} - X_{(2)}, \ldots, X_{(n)} - X_{(n-1)} \) with \( X_{(0)} = 0 \). Define a random variable \( \nu \) as follows: \( \nu = k \) iff \( X_{(k)} - X_{(k-1)} \leq X_{(i)} - X_{(i-1)}, \quad i = 1, 2, \ldots, n \). It is clear that \( \nu \) is the index of a spacing having minimal length. Let \( Y_1, Y_2, \ldots, Y_m \) be another sample from nonnegative random variable \( Y \) with continuous d.f. \( G \).

It is clear that \( S_m(r, s) \) denotes the number of \( X_i \)'s falling above the threshold \( X_u(r) \) and below the threshold \( X_u(s) \).

Let \( S_m \) be a number of observations \( Y_1, Y_2, \ldots, Y_m \) falling above the random threshold \( X_{(\nu-1)} \) and below the threshold \( X_{(\nu)} \). It is clear that in case \( F = G \) the second sample \( Y_1, Y_2, \ldots, Y_m \) can be interpreted as a continuation \( X_{n+1}, X_{n+2}, \ldots, X_{n+m} \) of the first sample \( X_1, X_2, \ldots, X_n \).

**Theorem 1.** The asymptotic distribution of \( \frac{S_m}{m} \) for large \( m \) is
\[
\lim_{m \to \infty} \sup_{0 \leq x \leq 1} \left| P \left\{ \frac{S_m}{m} \leq x \right\} - P \left\{ G(X_{(\nu)}) - G(X_{(\nu-1)}) \leq x \right\} \right| = 0.
\]

**Proof.** By definition
\[
S_m = \sum_{i=1}^{m} \xi_i = \sum_{i=1}^{m} I_{(X_{(\nu-1)}, X_{(\nu)})(X_{n+i})}, \tag{3}
\]
where \( I_B(x) = \begin{cases} 
1 & \text{if } x \in B \\
0 & \text{if } x \notin B 
\end{cases} \). Using the representation (3) one has

\[
P \left\{ \frac{S_m}{m} \leq x \right\} = P \left\{ \frac{1}{m} \sum_{i=1}^{m} I_{(X_{(n-1)}, X_{(i)})}(X_{n+i}) \leq x \right\}
\]

\[
= P \left\{ \int_{-\infty}^{\infty} I_{(X_{(n-1)}, X_{(i)})}(u)dG_m^*(u) \leq x \right\}
\]

(4)

where \( G_m^*(u) \) is the empirical distribution function constructed by the sample \( X_{n+1}, X_{n+2}, \ldots, X_{n+m} \) of size \( m \). Note that \( G_m^* \) and \( X_1, X_2, \ldots, X_n \) are independent random variables and \( X_1(\omega), X_2(\omega), \ldots, X_n(\omega), X_{n+1}(\omega), \ldots, X_{n+m}(\omega) \) is considered as a sequence of i.i.d. random variables defined in probability space \( \{\Omega, \mathcal{F}, P\} \), where \( \Omega \) is a set of points, \( \mathcal{F} \) is a \( \sigma \)-field of subsets of \( \Omega \), and \( P \) is a probability measure given in \( \mathcal{F} \). Denote

\[
H^*(G) = \int_{-\infty}^{\infty} I_{(x,y)}(u)dG(u), \quad (x < y, \ x, y \ \text{are fixed})
\]

\[
H(G) = \int_{-\infty}^{\infty} I_{(X_{(k-1)}, X_{(k)})}(u)dG(u).
\]

\( H(G) = H(G)(\omega) \) is a random variable defined in a probability space \( \{\Omega, \mathcal{F}, P\} \).

By using Glivenko-Cantelli theorem one can observe that \( H^*(G_m^*) \rightarrow H^*(G) \) almost surely. From (4) it follows that

\[
P \left\{ \frac{S_m}{m} \leq x \right\} = \sum_{k=1}^{n} P \left\{ \int_{-\infty}^{\infty} I_{(X_{(k-1)}, X_{(k)})}(u)dG_m^*(u) \leq x, \nu = k \right\}
\]

\[
= \sum_{k=1}^{n} P \left\{ \int_{-\infty}^{\infty} I_{(X_{(k-1)}, X_{(k)})}(u)dG_m^*(u) \leq x, X(k) - X(k-1) \leq X(i) - X(i-1), \right. \]

\[
i = 1, 2, \ldots, n \} = \sum_{k=1}^{n} \int_{-\infty}^{x} \int_{-\infty}^{y} P \left\{ \int_{-\infty}^{\infty} I_{(X_{(k-1)}, X_{(k)})}(u)dG_m^*(u) \leq x, X(k) - X(k-1) \leq X(i) - X(i-1), \right. \]

\[
\left. \leq X(i) - X(i-1), i = 1, 2, \ldots, n \right\} dF_{k-1,k}(x, y), \quad (5)
\]

where \( F_{k-1,k}(x, y) \) is the joint distribution function of \( (X_{(k-1)}, X_{(k)}) \). After simplifying (5) it follows that

\[
P \left\{ \frac{S_m}{m} \leq x \right\} = \ldots
\]
\[
\sum_{k=1}^{n} \int_{-\infty}^{y} \int_{-\infty}^{x} P \left\{ \int_{-\infty}^{\infty} I(x,y)(u) dG^n(u) \leq x, x-y \leq X_{(i)} - X_{(i-1)}, i = 1, 2, \ldots, n, \right\} = 1 \frac{1}{P\{X_{(k-1)} = x, X_{(k)} = y\}} dF_{k-1,k}(x,y)
\]

\[
= \sum_{k=1}^{n} \int_{-\infty}^{x} \int_{-\infty}^{y} P \left\{ \int_{-\infty}^{\infty} I(x,y)(u) dG^n(u) \leq x \right\} P \left\{ x - y \leq X_{(i)} - X_{(i-1)}, i = 1, 2, \ldots, n, \right\} = 1 \frac{1}{P\{X_{(k-1)} = x, X_{(k)} = y\}} dF_{k-1,k}(x,y) \quad \text{a.s.}
\]

\[
= \sum_{k=1}^{n} \int_{-\infty}^{x} \int_{-\infty}^{y} P \left\{ \int_{-\infty}^{\infty} I(x,y)(u) dG(u) \leq x, x-y \leq X_{(i)} - X_{(i-1)}, i = 1, 2, \ldots, n, \right\} = 1 \frac{1}{P\{X_{(k-1)} = x, X_{(k)} = y\}} dF_{k-1,k}(x,y)
\]

\[
= \sum_{k=1}^{n} P \left\{ \int_{-\infty}^{\infty} I(x_{(i)}, x_{(k)}) dG(u) \leq x, x_{(k)} - X_{(i)} \leq X_{(i)} - X_{(i-1)}, i = 1, 2, \ldots, n \right\} = P \left\{ G(X_{(i)}) - G(X_{(i-1)}) \leq x \right\}.
\]

(Note that expressions of type \( \frac{1}{P\{X_{(k-1)} = x, X_{(k)} = y\}} \) above should be understood as
\[
\lim_{h \to 0} \frac{1}{P\{x \leq X_{(k-1)} < x+h, y \leq X_{(k)} < y+h\}}.
\]

Theorem thus proved.

Remark 1. Let \( F(x) = G(x) = 1 - \exp(-\lambda x), \ x \geq 0. \) Then
\[
P \left\{ F(X_{(\nu)}) - F(X_{(\nu-1)}) \leq x \mid \nu = 1 \right\} = 1 - (1-x)^{a_{\nu+1}} \quad 0 \leq x \leq 1.
\]
Proof. In fact by definition of $\nu$ one has

$$P \{ F(X_\nu) - F(X_{\nu-1}) \leq x \mid \nu = 1 \} = \frac{P \{ F(X_\nu) - F(X_{\nu-1}) \leq x, \nu = 1 \}}{P \{ \nu = 1 \}}.$$  

Consider

$$P \{ F(X_\nu) - F(X_{\nu-1}) \leq x, \nu = 1 \} = P \{ F(X(1)) - F(X(0)) \leq x, \nu = 1 \}$$

$$= P \{ F(X(1)) \leq x, X(1) \leq X(2), \ldots, X(1) \leq X(n) - X(n-1) \}$$

$$= P \{ F(X(1)) \leq x, X(1) \leq X(2) - X(1), \ldots, X(1) \leq X(n) - X(n-1) \mid X(1) = t \} dF_1(t)$$

$$= n\lambda F(t) \leq x (e^{-\lambda t}) \frac{\nu(n+1)}{2} dt = n\lambda_0 \frac{\nu}{\lambda} \ln(1-x) (e^{-\lambda t}) \frac{\nu(n+1)}{2} dt$$

$$= \frac{2}{n+1} (1 - (1-x)^{\frac{\nu(n+1)}{2}}), 0 \leq x \leq 1.$$

After some algebra, using $P \{ \nu = 1 \} = \frac{2}{n+1}$ one obtains

$$P \{ F(X_\nu) - F(X_{\nu-1}) \leq x \mid \nu = 1 \} = 1 - (1-x)^{\frac{\nu(n+1)}{2}}, 0 \leq x \leq 1.$$

Lemma 1. Let $X_1, X_2, X_3$ i.i.d. random variables with continuous d.f. $F$. Let $X_{(\nu)} - X_{(\nu-1)} \leq X_{(i)} - X_{(i-1)}, i = 2, 3$. The p.d.f. of random variable $F(X_\nu) - F(X_{\nu-1})$ is

$$f^*(t) = 6 \int_1^t [1 - F(2F^{-1}(v) - F^{-1}(v - t)) + F(2F^{-1}(v - t) - F^{-1}(v))] dv$$

$$0 < t < 1.$$  

Proof. The d.f. of random variable $F(X_\nu) - F(X_{\nu-1})$ can be found as follows:

$$F^*(t) = P \{ F(X_\nu) - F(X_{\nu-1}) \leq t \} = \int \int_C f_{\nu-1, \nu}(x, y) dxdy \quad (6)$$

where $C = \{(x, y) : x < y, F(y) - F(x) \leq t \}$ and $f_{\nu-1, \nu}(x, y)$ is the joint p.d.f. of $X_{(\nu-1)}$ and $X_{(\nu)}$. It is known that

$$f_{\nu-1, \nu}(x, y) = 6f(x)f(y)[1 - F(2y - x) + F(2x - y)], \quad x < y \quad (7)$$
(c.f., David (1981)).

Let us take in (6) \( F(x) = u \) and \( F(y) = v \). The Jacobian of this transformation is equal to \( (f(F^{-1}(u))f(F^{-1}(v)))^{-1} \). Then from (6) using (7) one has

\[
F^*(t) = 6 \int_0^t \int_0^v [1 - F(2F^{-1}(v) - F^{-1}(u)) + F(2F^{-1}(u) - F^{-1}(v))] \, du \, dv
\]

\[
+ 6 \int_t^1 \int_{v-t}^1 [1 - F(2F^{-1}(v) - F^{-1}(u)) + F(2F^{-1}(u) - F^{-1}(v))] \, du \, dv.
\]

The proof is completed by differentiating \( F^*(t) \) with respect to \( t \).

**Example.** Let \( X_1, X_2, X_3 \) be a sample from uniform on \((0, 1)\) distribution. Then

\[
f^*(t) = \begin{cases} 
6(2t - 1)^2, & 0 < t < \frac{1}{2} \\
0, & \text{otherwise}
\end{cases}
\]

In fact, from Lemma 1 we have

\[
f^*(t) = 6 \int_t^1 dv - 6 \int_t^1 F(v + t)dv + 6 \int_t^1 F(v - 2t)dv.
\]

It is evident that

\[
F(v + t) = \begin{cases} 
0 & \text{if } v \leq -t \\
v + t & \text{if } -t < v < 1 - t
\end{cases},
F(v - 2t) = \begin{cases} 
0 & \text{if } v \leq 2t \\
v - 2t & \text{if } 2t < v < 1 + 2t
\end{cases}.
\]

Let \( 0 < t < \frac{1}{2} \). Then \( t < 1 - t \) and one has

\[
6 \int_t^1 F(v + t)dv = 6 \int_t^{1-t} (v + t)dv + 6 \int_{1-t}^1 dv = 3 - 12t^2 + 6t,
\]

\[
6 \int_t^1 F(v - 2t)dv = 6 \int_{2t}^1 (v - 2t)dv = 3 - 12t + 12t^2.
\]
Let $\frac{1}{2} < t < 1$. Then $t > 1 - t$, $F(v + t) = 1$, $F(v - 2t) = 0$ and one has

$$6 \int_t^1 F(v + t) dv = 6 \int_t^1 dv = 6(1 - t), \quad (11)$$
$$6 \int_t^1 F(v - 2t) dv = 0.$$  

Using (10) and (11) in (9) one obtains (8).

It is clear that in this case the d.f. of $F(X(\nu)) - F(X(\nu - 1))$ is

$$F^*(t) = \begin{cases} 8t^3 - 12t^2 + 6t, & 0 < t < 1/2 \\ 1, & t \geq 1/2 \end{cases}$$

Lemma 2. Let $X_1, X_2, ..., X_n$ i.i.d r.v.’s with d.f. $F(x) = 1 - \exp\{-\lambda x\}, x > 0, \lambda > 0$ and $(X(\nu - 1), X(\nu))$ is minimal spacing of this sample. In this case the d.f. of random variable $X(\nu) - X(\nu - 1)$ is

$$P\{X(\nu) - X(\nu - 1) \leq x\} = 1 - \exp\left\{-\frac{n(n + 1)}{2} \lambda x\right\}, \quad x > 0.$$  

Remark 2. Let $X_1, X_2, ..., X_n$ i.i.d r.v.’s with d.f. $F$. If $F$ is exponential d.f. with parameter $\lambda$ then

$$\frac{n + 1}{2} (X(\nu) - X(\nu - 1)) \overset{d}{=} X(1)$$  

3. RECORD STATISTICS

Let $\{X_n\}_{n \geq 1}$ be a sequence of i.i.d r.v.’s with continuous distribution function $F$. Define a record times of this sequence as follows: $u(1) = 1$, $u(n) = \min j : j > u(n - 1), \ X_j > X_{u(n - 1)}, n > 1$. Let $X_{u(1)}, X_{u(2)}, ...$ be corresponding record values.

The d.f. and probability density function (p.d.f.) of record values can be expressed in terms of

$$R(x) = -\ln(1 - F(x)) \quad \text{and} \quad r(x) = \frac{d}{dx} R(x) = \frac{f(x)}{1 - F(x)}.$$  

8
It is known that the distribution of \( n \) th record value is

\[
F_n(x) = P \{ X_{u(n)} \leq x \} = \int_{-\infty}^{x} \frac{R_{n-1}(u)}{(n-1)!} dF(u) \quad , -\infty < x < \infty.
\]

The joint p.d.f. of \( X_{u(i)} \) and \( X_{u(j)} \) is

\[
f(x_i, x_j) = \frac{(R(x_i))^{j-1} \cdot r(x_i) \cdot (R(x_j) - R(x_i)))^{i-1}}{(i-1)! \cdot (j-i-1)!} \cdot f(x_j) \quad , -\infty < x_i < x_j < \infty
\]

Let \( X_{u(n)} \) be the \( n \) th record value of a sequence of i.i.d. r.v.’s. Suppose that \( X_{u(n)+1}, X_{u(n)+2}, ..., X_{u(n)+m} \) be the \( m \) observations that succeed \( X_{u(n)} \).

For \( i = 1, 2, ..., m \) and \( 1 \leq r < s \leq n \), it is known that

\[
P \{ X_{u(n)+i} \in (X_{u(r)}, X_{u(s)}) \} = \frac{1}{2^r} - \frac{1}{2^s}
\]

(c.f., Bairamov (1997)).

Define the random variables \( \xi_1, \xi_2, ..., \xi_m \) as follows:

\[
\xi_i = \begin{cases} 
1 & \text{if } X_{u(n)+i} \in (X_{u(r)}, X_{u(s)}) \\
0 & \text{if } X_{u(n)+i} \notin (X_{u(r)}, X_{u(s)})
\end{cases}, \quad i = 1, 2, ..., m \quad , \quad r < s.
\]

Denote

\[
\nu_m = \sum_{i=1}^{m} \xi_i
\]

\( \nu_m \) is the number of observations \( X_{u(n)+1}, X_{u(n)+2}, ..., X_{u(n)+m} \) falling into interval \( (X_{u(r)}, X_{u(s)}) \). It is clear that the r.v.’s \( \xi_1, \xi_2, ..., \xi_m \) are dependent. Bairamov and Eryilmaz (2000) show that for \( r = k - 1 \) and \( s = k \) \((k = 2, ..., n)\)

\[
P \{ \nu_m = j \} = \binom{m}{j} \sum_{i=0}^{m-j} (-1)^i \binom{m-j}{i} \frac{1}{(j+i+1)^k} 
\]

\( j = 0, 1, ..., m. \)
Let $\{X_n\}_{n \geq 1}$ be a sequence of i.i.d. r.v.’s with continuous d.f. $F$, $X_{u(1)}, X_{u(2)}, ...$ is a sequence of record values. Let $X'_1, X'_2, ..., X'_m$ be i.i.d. random variables with continuous d.f. $G$. Define the following random variables

$$
\xi^+_i(r, s) = \begin{cases} 
1 & \text{if } X'_i \in (X_u(r), X_u(s)) \\
0 & \text{if } X'_i \notin (X_u(r), X_u(s))
\end{cases}, \quad i = 1, 2, ..., m, \quad r < s.
$$

and let

$$
S_m(r, s) = \sum_{i=1}^{m} \xi^+_i(r, s).
$$

It is clear that $S_m(r, s)$ denotes the number of $X'_i$’s falling above the threshold $X_u(r)$ and below the threshold $X_u(s)$. It is true that

$$
\lim_{m \to \infty} \sup_{0 \leq x \leq 1} \left| \frac{S_m(r, s)}{m} - P \{ F(X_u(s)) - F(X_u(r)) \leq x \} \right| = 0.
$$

The case $F = G$ is of interest on its own and we have the following results for this case:

Let $F = G$. Then

$$
\lim_{m \to \infty} \sup_{0 \leq x \leq 1} \left| \frac{S_m(r, s)}{m} - P \{ F(X_u(s)) - F(X_u(r)) \leq x \} \right| = 0.
$$

where $U_{rs} = F(X_u(s)) - F(X_u(r))$ has d.f.

$$
P \{ U_{rs} \leq x \} = \frac{1}{(r-1)!(s-r-1)!} \int_{0}^{x} \int_{0}^{1-t_2} \left[ \ln \frac{1}{1-t_2} \right]^{r-1} \frac{1}{1-t_2} \times
$$

$$
\times \left[ \ln \frac{1-t_1}{1-t_1-t_2} \right]^{s-r-1} dt_2 dt_1,
$$

and p.d.f.

$$
f_{U_{rs}}(x) = \frac{1}{(r-1)!(s-r-1)!} \int_{0}^{1-x} \left[ \ln \frac{1}{1-t_2} \right]^{r-1} \frac{1}{1-t_2} \left[ \ln \frac{1-x}{1-x-t_2} \right]^{s-r-1} dt_2,
$$

$$
0 < x < 1.
$$

Now let again $F = G$ and $r = k - 1, s = k$ ($k = 2, ..., n$). Then the expected value and the variance of $S_m(r, s)$ is:

$$
ES_m(k-1, k) = m/2^k,
$$

10
\[ \text{Var} S_m(k - 1, k) = m(1/2^k - 1/3^k) + m^2(1/3^k - 1/2^{2k}). \]

Let \( F = G. \) For \( r = k - 1 \) and \( s = k \) \((k = 2, 3, \ldots, n)\). Then

\[
\lim_{m \to \infty} \sup_{0 \leq x \leq 1} \left| P \left\{ \frac{S_m(r, s)}{m} \leq x \right\} - P \left\{ U_{k-1,k} \leq x \right\} \right| = 0,
\]

where \( U_{k-1,k} = F(X_{u(k)}) - F(X_{u(k-1)}) \) has d.f.

\[
D_k(x) \equiv P \{ U_{k-1,k} \leq x \} = \frac{1}{(k-1)!} \int_{0}^{x} \left[ \ln \frac{1}{u} \right]^{k-1} du, \quad 0 < x < 1.
\]

and p.d.f.

\[
d_k(x) \equiv f_{U_{k-1,k}}(x) = \frac{1}{(k-1)!} \left[ \ln \frac{1}{x} \right]^{k-1}, \quad 0 < x < 1.
\]

Also it is true that

\[
P \left\{ \frac{S_m(k - 1, k) - ES_m(k - 1, k)}{\sqrt{\text{Var} S_m(k - 1, k)}} \leq x \right\} \to_{m \to \infty} D_k(ax + b),
\]

where

\[
a = \sqrt{\frac{1}{3^k} - \frac{1}{2^{2k}}} \quad \text{and} \quad b = \frac{1}{2^k}.
\]

**Remark 3.** Let \( \{X_n\}_{n \geq 1} \) be a sequence of i.i.d. r.v.’s with continuous d.f. \( F, X_{u(1)}, X_{u(2)}, \ldots \) be corresponding upper record values and \( X_{L(1)}, X_{L(2)}, \ldots \) be corresponding lower record values of this sequence. If \( F \) is uniform d.f. on \((0, 1)\) then

\[
X_{L(k)} \stackrel{d}{=} X_{u(k)} - X_{u(k-1)}
\]
